### 1 Results & Discussion

#### 1.1 The Discrete Fourier Transform (DFT)

Given a signal, x[n], it's N-point DFT is given by

$$X_k = \sum_{n=0}^{N-1} x[n] W_N^{kn},$$
(1)

where  $W_N = e^{-j2\pi/N}$ . The discrete Fourier transform is the sampled version of the discrete time Fourier transform (DTFT), which is a continuous function. More specifically, the *N*-point DFT contains *N* samples from the continuous DTFT.

For example, consider the signal  $x[n] = (-1)^n$  for  $0 \le n \le N-1$ . By evaluating the sum shown in equation 1 as a truncated geometric series, the *N*-point DFT of x[n] can be found. All truncated geometric series are evaluated as

$$\sum_{k=0}^{n-1} ar^k = \begin{cases} an & r=1\\ a\left(\frac{1-r^n}{1-r}\right) & r \neq 1 \end{cases},$$
(2)

where r is the common ratio between adjacent terms. For the N-point DFT of x[n], the common ratio is  $-W_N^k$ , which takes a value of 1 for  $k = \frac{N}{2}$ . Therefore, the N-point DFT of x[n] is

$$X[k] = \begin{cases} N & k = \frac{N}{2} \\ \left(\frac{1 - (-W_N^k)^N}{1 - (-W_N^k)}\right) & k \neq \frac{N}{2} \end{cases}$$
(3)

The N-point DFT of x[n], where N = 8 is seen in figure 1. It only has a non-zero value for  $k = \frac{N}{2} = 4$ . This is the case for all even-number-point DFTs. Therefore, only odd-number-point DFTs should be used. For example, the 9-point DFT of x[n], where N = 8 is seen in figure 2. While equation 3 cannot be used

Figure 1: The N-point DFT of x[n], where N = 8

because there are a different number of samples for the DFT and the input signal, the overall DFT is more useful than the 8-point DFT.

#### 1.2 The Z-Transform

Given a discrete signal, x[n], its z-transform is given by

$$X(z) = \sum_{n} x[n] z^{-n} \tag{4}$$

Figure 2: The 9-point DFT of x[n], where N = 8

where z is a complex variable. The Z-transform of any discrete signal is a continuous function. Therefore, any attempt to calculate the Z-transform with a digital computer requires sampling or symbolic math. Symbolic math is quite a powerful tool, and others have worked hard to implement the Z-transform as a symbolic function. In MATLAB, this function is ztrans.

The Z-transform of the following signals can be found very quickly using this method:

$$\begin{aligned} x_1[n] &= a^n u[n] \\ x_2[n] &= (n+1)a^n u[n] \\ x_3[n] &= a^n \cos(bn)u[n] \\ \mathcal{Z}\{x_1[n]\} &= -\frac{z}{a-z} \\ \mathcal{Z}\{x_2[n]\} &= \frac{az}{(a-z)^2} - \frac{z}{a-2} \\ \mathcal{Z}\{x_3[n]\} &= -\frac{z(\cos(b)-z/a)}{a\frac{z^2}{a^2} - \frac{2z\cos(b)}{a} + 1} \end{aligned}$$

#### 1.3 The Inverse Z-Transform

Similarly, the inverse Z-transform also benefits from using a symbolic calculator. For example, the inverse Z-transform of the following can be found rapidly:

$$\begin{aligned} \mathcal{Z}\{x_4[n]\} &= \frac{z}{z+0.5} \\ \mathcal{Z}\{x_5[n]\} &= \frac{z^2}{(z-0.8)^2} \\ \mathcal{Z}\{x_6[n]\} &= \frac{z}{(z+0.3)(z+0.6)^2} \\ x_4[n] &= (-1/2)^n \\ x_5[n] &= 2(4/5)^n (n-1)(4/5)^n \\ x_6[n] &= \frac{50n(-3/5)^n - 100(-3/5)^n + 100(-3/10)^n}{9} \end{aligned}$$

## 2 Conclusions

Overall understanding tricks for calculating geometric sums is very helpful for calculating DFTs. It is also important to use odd-number-point DFTs only, as taking an even number of samples forces almost all values to go to zero. As for Z-transforms and inverse Z-transforms, knowing how to use symbolic computation makes finding them quite easy. Additionally, symbolic computation allows for the easy manipulation of how simplified or expanded the result is.
